

# A Case of the Week

## Case 423

A seventy-six-year-old male presented with paresis of left lower extremities and dizziness. He got a bruise on his head two months ago that was not identified in detail. One month ago, he came to our hospital for sudden dizziness but did not expect to get further investigation. This morning, he could not raise his lower extremities. He stumbled and almost fell down since he could not step forwards with his left lower extremities. He got brain CT for further examination (Figs. 1, 2).

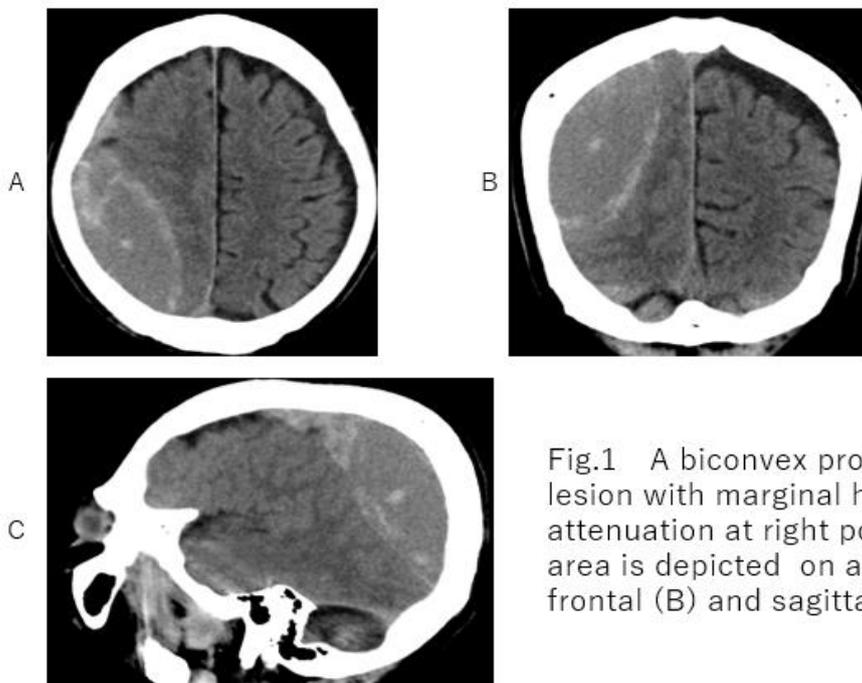

Fig.1 A biconvex protruding lesion with marginal high attenuation at right posterior area is depicted on axial (A), frontal (B) and sagittal (C) CT.

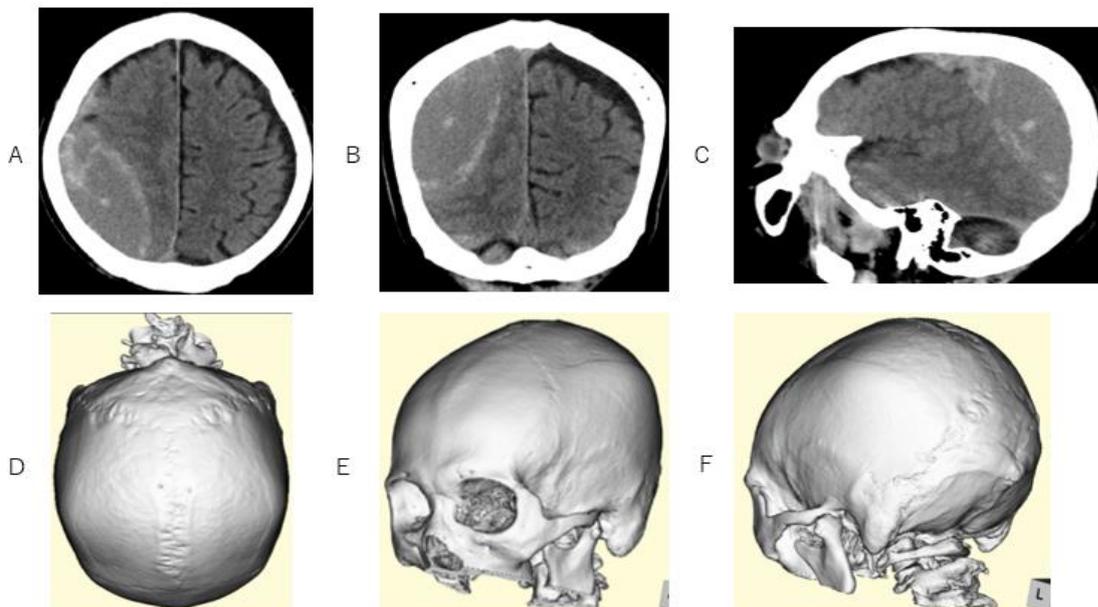

Fig.2 Compared with volume-rendered imaging, a bilateral convex lesion is bordered by cranial sutures. In other word, the extension of the lesion is blocked corresponded with cranial suture.

## What is possible imaging diagnosis?

---

- 1. Subdural hematoma**
- 2. Epidural hematoma**
- 3. Subarachnoid hemorrhage**
- 4. Brain contusion**
